Introduction to Graph Theory

Introduction to Graph Theory

- Much like group theory is the mathematical language of symmetry, graph theory provides languages for expressing relationships

Applications of graph theory

- Modeling networks
- Chemistry
- Machine learning
- Routing problems
- CYOA

2026-06-30

└ Networks and Relationships

- Much like group theory is the mathematical language of symmetry, graph theory provides languages for expressing relationships

Applications of graph theory

- Modeling networks
- Chemistry
- Machine learning
- Routing problems
- CYOA

- A **graph** $\mathcal{G} = (V, E)$ is a set V of **vertices** together with a set E of **edges**. Two vertices are **adjacent** or neighbors if they are connected by an edge.
- A **simple graph** is a graph with at most one edge between any pair of vertices and no loops.

(a) A graph that is not simple.

(b) A simple graph.

- A **graph** $G = (V, E)$ is a set V of **vertices** together with a set E of **edges**. Two vertices are **adjacent** or neighbors if they are connected by an edge.
- A **simple graph** is a graph with at most one edge between any pair of vertices and no loops.

- A friendship graph is a graph where each pair of vertices have exactly one neighbor (i.e., the "friend") in common.

Example (Friendship graphs)

Draw examples of friendship graphs.

└ Friendship

- A friendship graph is a graph where each pair of vertices have exactly one neighbor (i.e., the "friend") in common.

Example (Friendship graphs)

Draw examples of friendship graphs.

- The **degree** of a vertex is the number of edges adjacent to that vertex. A **path** between two vertices is a series of distinct, adjacent vertices that connects the vertices. A **cycle** is a path that starts and ends at the same vertex.

Example (Finding degrees, paths and cycles)

Find the following using the graph below:

1. The degree of each vertex.
2. The number of paths from vertex 1 to vertex 6.
3. The length of the shortest path from vertex 1 to vertex 6.

Figure 2: A graph that is not simple.

1. The degree of each vertex.
2. The number of paths from vertex 1 to vertex 6.
3. The length of the shortest path from vertex 1 to vertex 6.

Figure 2: A graph that is not simple.

Example (Scheduling tournaments)

Suppose six teams are playing in a tournament and each team must play exactly three others. How can this be done? What if only five teams are playing?

└ An Application

Example (Scheduling tournaments)

Suppose six teams are playing in a tournament and each team must play exactly three others. How can this be done? What if only five teams are playing?

An Impossibility Proof

Example (Not scheduling tournaments)

Prove that it's impossible to schedule a tournament for five teams such that each team plays exactly three others.

Graph Theory Notes

└ Introduction to Graph Theory

└ An Impossibility Proof

Look at previous examples and try to find a relationship between degrees and edges.

Example (Utility graph)

Three houses A , B and C must be connected to three utilities E (electric), G (gas) and W (water). Each house must be connected to each utility exactly once. What graph represents this situation?

Example (Utility graph)

Three houses A , B and C must be connected to three utilities E (electric), G (gas) and W (water). Each house must be connected to each utility exactly once. What graph represents this situation?

- A **bipartite graph** is a graph with one group of m vertices and another group of n vertices such that each vertex is adjacent to all of the vertices in the other group and adjacent to none of the vertices in their own group. This graph is denoted by $K_{m,n}$.
- The utility graph is $K_{3,3}$.

- A **bipartite graph** is a graph with one group of m vertices and another group of n vertices such that each vertex is adjacent to all of the vertices in the other group and adjacent to none of the vertices in their own group. This graph is denoted by $K_{m,n}$.
- The utility graph is $K_{3,3}$.

Example (Employment)

Suppose that four employers (labeled A, B, C, D) are recruiting from a shared pool of four applicants (labeled $1, 2, 3, 4$). The employers and applicants have ranked each other as follows:

Applicant	Employer rankings	Employer	Applicant rankings
1	A, B, C, D	A	4, 2, 1, 3
2	A, B, D, C	B	2, 1, 3, 4
3	B, A, C, D	C	1, 3, 4, 2
4	D, A, B, C	D	1, 3, 2, 4

Employers will make offers to applicants, but applicants are allowed to change their minds if a better offer comes along. Is there a *stable matching*, i.e., a situation where no applicant will change their mind?

2026-06-30

Stable Matchings

Example (Employment)

Suppose that four employers (labeled A, B, C, D) are recruiting from a shared pool of four applicants (labeled $1, 2, 3, 4$). The employers and applicants have ranked each other as follows:

Applicant	Employer rankings	Employer	Applicant rankings
1	A, B, C, D	A	4, 2, 1, 3
2	A, B, D, C	B	2, 1, 3, 4
3	B, A, C, D	C	1, 3, 4, 2
4	D, A, B, C	D	1, 3, 2, 4

Employers will make offers to applicants, but applicants are allowed to change their minds if a better offer comes along. Is there a *stable matching*, i.e., a situation where no applicant will change their mind?

An example of an unstable matching is the following:

Figure 3: A matching that is not stable.

This is because A prefers 2 to 1 and 2 prefers A to B . Therefore, both are inclined to switch.

- The previous problem can be solved by an algorithm. For each round:
 1. Each employer with an open position makes an offer to the best candidate that they haven't made an offer to yet.
 2. Each applicant evaluates their offers and tentatively selects the best offer while rejecting the others.
 3. If there are any open positions remaining, then repeat this process in a new round of offers.

- The previous problem can be solved by an algorithm. For each round:
 1. Each employer with an open position makes an offer to the best candidate that they haven't made an offer to yet.
 2. Each applicant evaluates their offers and tentatively selects the best offer while rejecting the others.
 3. If there are any open positions remaining, then repeat this process in a new round of offers.

This is known as the Gale-Shapley algorithm. It had previously been used to match residents with hospitals.
